Online Appendix — Votes Without Neighborhoods

This appendix gives the formal framework and proofs (A), the data (B), the results cited in the text (C) and the re-implementation of a published allocation (D). Further tables, and the code that produces every number, are in the replication files.

A. Formal framework, proofs and computation

Parameters and symbols. η: uniform movement cap (share of a station's ballots cast by non-residents beyond the movement the roll forces); λ: multiple of the mobility-calibrated cap; δ: tolerance for residents' out-of-zone composition around their station; s: tolerance for residents' early composition beyond their station's own departure from the benchmark a^F; t: tolerance for movers' composition around their home station; κ: bound on the within-jurisdiction slope of residents' early-vote departures on log price (Section 4.5). s^*, λ^*, η^*, δ^*, κ^*: the largest value of each parameter at which the lower bound of a slope stays positive. z: roll-based share; y: valid-vote share. Columns A–F: the assumption sets of Table 2.

A.1 Observables, unknowns and the polytope

Consider one counting jurisdiction g: a district (gu), or a National Assembly constituency in 2024 (48 units). It contains neighborhoods (dongs) i and in-zone early stations j, one per dong. Ballot categories c are candidates and invalid ballots. The returns and the roll give, for each dong, election-day ballots A_{ic} (cast by residents of i), in-zone early ballots K_{jc} counted at station j, the certified electorate E_i and the electorate remaining on the election-day roll D_i, which is printed after early voting with early voters marked and excludes residents registered for at-home, shipboard or overseas voting. $E_i - D_i$ is the number of residents removed from the election-day roll. Jurisdiction totals are the out-of-zone early ballots P_c, the at-home, shipboard and overseas ballots Q_c, and $U = \sum_i (E_i - D_i) - \sum_j K_j - \sum_c P_c - \sum_c Q_c$, the removed residents who cast no counted ballot. Write $A_i = \sum_c A_{ic}$, $K_j = \sum_c K_{jc}$, $H_i = A_i + E_i - D_i$ and $r_j = \max\{0, K_j - (E_j - D_j)\}$.

The unknowns are F_{ijc} (in-zone early ballots of residents of i cast at j), P_{ic} and Q_{ic} (residents' pooled ballots) and U_i (removed residents who did not vote), all non-negative and subject to

$$\sum_{j,c} F_{ijc} + \sum_c P_{ic} + \sum_c Q_{ic} + U_i = E_i - D_i, \tag{R}$$

$$\sum_i F_{ijc} = K_{jc}; \quad \sum_i P_{ic} = P_c; \quad \sum_i Q_{ic} = Q_c; \quad \sum_i U_i = U, \tag{S}$$

$$F_{ijc} = 0 \ \text{ if } i \text{ and } j \text{ lie in different early-voting zones.} \tag{Z}$$

Residents' count of category c is $N_{ic} = A_{ic} + \sum_j F_{ijc} + P_{ic} + Q_{ic}$. The roll-based share is $z_{ic} = N_{ic}/H_i$ and the valid-vote share $y_{ic} = N_{ic}/(H_i - U_i - N_{i,\text{inv}})$.

Restrictions. (M_η) caps non-resident ballots at station j at $r_j + \eta K_j$; the mobility-calibrated scenario caps them at $r_j^\rho + \lambda C_j$, with $r_j^\rho = \max\{r_j, K_j - \phi_u(E_j - D_j)\}$, ϕ_u the zone's ratio of in-zone early ballots to removed residents, and C_j the calibrated cross-dong flow (B.4). (A_δ) bounds residents' out-of-zone composition around an anchor $\tilde{a}_{ic}$: $(\tilde{a}_{ic} - \delta)P_{i\cdot} \le P_{ic} \le (\tilde{a}_{ic} + \delta)P_{i\cdot}$, with $\tilde{a}_{ic} = K_{ic}/K_i$ (the station's composition; in 2012, without in-zone early voting, the election-day composition), or the station composition shifted by the jurisdiction's out-of-zone minus in-zone early composition, optionally plus its price relation. (A_s^F) bounds residents' in-zone early composition around $a_{ic}^F = \mathrm{clip}_{[0,1]}(A_{ic}/A_i + \gamma_{gc}^K)$, with γ_{gc}^K the jurisdiction's in-zone early minus election-day composition:

$$(a_{ic}^F - \omega_{ic}) \sum_{j,c'} F_{ijc'} \le \sum_j F_{ijc} \le (a_{ic}^F + \omega_{ic}) \sum_{j,c'} F_{ijc'}, \qquad \omega_{ic} = |K_{ic}/K_i - a_{ic}^F| + s,$$

with the lower limit truncated at zero. (A_l^{mv}) bounds movers: with $k_{ic} = K_{ic}/K_i$, $(k_{ic} - t) \sum_{j\neq i,c'} F_{ijc'} \le \sum_{j\neq i} F_{ijc} \le (k_{ic} + t) \sum_{j\neq i,c'} F_{ijc'}$. ($\mathrm{A}^\kappa$) bounds the alignment of residents' early-vote departures with price. Let $\Delta_i = \sum_j F_{ij,\mathrm{cons}} - a_{i,\mathrm{cons}}^F \sum_{j,c} F_{ijc} + P_{i,\mathrm{cons}} - \tilde{a}_{i,\mathrm{cons}} P_{i\cdot}$, let I_u be the dongs of counting jurisdiction u with a price (in 2024 a constituency, not a gu), $\bar{x}_u$ their mean log price, and $v_i = (x_i - \bar{x}_u) / \sum_{j\in I_u} (x_j - \bar{x}_u)^2$ for $i \in I_u$ and 0 otherwise, so that $\sum_{i\in u} v_i = 0$. Then $|\sum_{i\in u} v_i \Delta_i / H_i| \le \kappa$ for every u: the within-jurisdiction OLS slope of departures, as shares of the roll, on log price. (A_P^κ) is the same restriction on out-of-zone departures alone, $\Delta_i^P = P_{i,\mathrm{cons}} - \tilde{a}_{i,\mathrm{cons}} P_{i\cdot}$, used in place of ($\mathrm{A}_\delta$). The observed reference for κ applies the same weights to station departures $(K_{i,\mathrm{cons}} - a_{i,\mathrm{cons}}^F K_i)/H_i$. Λ is the set of non-negative unknowns satisfying (R), (S), (Z) and the imposed restrictions.

A.2 Results

Lemma 1. Under (R), (S) and non-negativity, $\sum_{i\neq j} \sum_c F_{ijc} \ge r_j$ for every j.

Proof. By (S), $\sum_{i\neq j} \sum_c F_{ijc} = K_j - \sum_c F_{jjc}$, and by (R) $\sum_c F_{jjc} \le E_j - D_j$. □

Corollary 1. Under (M_0), every dong j with $r_j > 0$ has $P_{j\cdot} = Q_{j\cdot} = U_j = 0$ and $F_{jk\cdot} = 0$ for $k \neq j$: its removed residents all voted at their own station.

Proof. Non-resident ballots at j are at most r_j, so $F_{jj\cdot} \ge K_j - r_j = E_j - D_j$, and (R) forces every other term to zero. □

Summing (R) over the dongs of a zone u and using (S) and (Z) gives a zone-level identity, $\sum_{i\in u}(P_{i\cdot} + Q_{i\cdot} + U_i) = \sum_{i\in u}(E_i - D_i) - \sum_{j\in u} K_j$.

Proposition 1. Suppose Λ is nonempty. It is a convex polytope. For any weights w, the set of values of $\sum_i w_i z_{ic}$ over Λ is $[\min_\Lambda, \max_\Lambda]$, each endpoint the value of a linear program.

Proof. All constraints are linear in the unknowns, and z_{ic} is linear because H_i is observed; a linear function on a convex polytope attains every value between its extremes. □

The bounds are sharp for the continuous relaxation, relative to the information in (R), (S), (Z) and the restrictions. Jurisdictions share no constraint, so citywide extrema are sums of jurisdiction-specific extrema.

Proposition 2. Let $w = w^{\mathrm{btw}} + w^{\mathrm{wth}}$ with $w_i^{\mathrm{btw}} = H_i \mu_{g(i)}$. (i) $\sum_i w_i^{\mathrm{btw}} z_{ic}$ is point-identified by the jurisdiction totals. (ii) The identified set of $\sum_i w_i z_{ic}$ is that number plus the identified set of $\sum_i w_i^{\mathrm{wth}} z_{ic}$. (iii) Without ($\mathrm{A}_\delta$), ($\mathrm{A}^\kappa$) and ($\mathrm{A}_P^\kappa$), if some point of Λ has $P_{ic'} > 0$ and $P_{i'c} > 0$ for dongs $i \neq i'$ and distinct ballot categories $c \neq c'$ in one jurisdiction, the slope is not point-identified whenever $w_i/H_i \neq w_{i'}/H_{i'}$. (iv) The width is at most $\sum_g (\max_{i\in g} w_i/H_i - \min_{i\in g} w_i/H_i) M_{gc}$, with $M_{gc} = P_{gc} + Q_{gc} + \sum_{j\in g} \min\{K_{jc}, m_j\}$ and m_j the movement cap.

Proof. (i) $\sum_{i\in g} N_{ic}$ equals the observed jurisdiction total. (ii) Linearity in w. (iii) Exchanging ε ballots between $(i,c),(i,c'),(i',c),(i',c')$ leaves every constraint unchanged and moves the slope by $\varepsilon(w_i/H_i - w_{i'}/H_{i'})$. (iv) Between two points of Λ, $\sum_{i\in g}(N_{ic} - N'_{ic}) = 0$ and the positive parts are bounded by M_{gc}, because both points keep at least $K_{jc} - m_j$ of station j's category-c ballots with its residents; hence $\sum_{i\in g}(w_i/H_i)(N_{ic} - N'_{ic}) \le \text{range}_g(w/H)\, M_{gc}$. □

Lemma 2. With $\pi_w = \sum_i (x_i - \bar{x}_{g(i)})^2 / \sum_i (x_i - \bar{x})^2$, the pooled OLS weights satisfy $w^P = \pi_w w^{FE} + v$, $v_i = (\bar{x}_{g(i)} - \bar{x}) / \sum_k (x_k - \bar{x})^2$, so for every $\ell \in \Lambda$, $\theta(w^P;\ell) = \pi_w \theta(w^{FE};\ell) + \theta(v;\ell)$.

Proof. Decompose $x_i - \bar{x}$ into within- and between-gu parts and use linearity. □

$\theta(v;\ell)$ is a gradient computed from residence-based dong shares; it is not the gradient of gu totals and depends on the allocation. It distinguishes the between-district component of a dong-level regression from a regression on fully counted district totals.

Proposition 3. Holding all other coefficients fixed, Λ weakly expands as we increase η, λ, δ, s and t, and when any restriction, including (Z), is removed; so the lower bound of a z slope is non-increasing in each parameter and breakdown points are well defined.

Proof. Each change relaxes inequalities or removes equalities. □

Proposition 4. With $T_i = H_i - U_i - N_{i,\text{inv}}$, $y_{ic} - z_{ic} = y_{ic}(U_i + N_{i,\text{inv}})/H_i$, so with dong bounds $\underline{y}_{ic} \le y_{ic} \le \bar{y}_{ic}$ over Λ, $w_i y_{ic} \ge w_i z_{ic} + k_i(U_i + N_{i,\text{inv}})/H_i$ with $k_i = w_i \underline{y}_{ic}$ $(w_i > 0)$ or $w_i \bar{y}_{ic}$ $(w_i < 0)$. The right side is linear, so one LP gives a valid lower bound on the valid-vote slope; the upper bound is symmetric.

Proof. $N/T - N/H = N(H-T)/(TH)$ and $(U_i + N_{i,\text{inv}})/H_i \ge 0$. □

A.3 Further quantities

The neighborhood contrast weights each dong priced above its gu's median by $\nu_g / n_g^{\text{high}}$ and every other dong with a price by $-\nu_g / n_g^{\text{low}}$, with ν_g proportional to the gu's number of dongs with a price.

The region of assumptions. $s^*(\lambda,\delta) = \sup\{s : \min_\Lambda \theta > 0\}$, found by bisection on $[s_{\min}, 0.30]$ (width $0.3/256$), where $s_{\min}$ is the smallest feasible slack; reported values are the lower end of the final interval.

The first reversing allocation along s attains the minimum slope at s just above s^*, holding λ and δ fixed. *The least-departure reversal* minimizes $\sum_i |\sum_j F_{ij,\text{cons}} - a^F_{i,\text{cons}} \sum_{j,c} F_{ijc}| + \sum_i |P_{i,\text{cons}} - \tilde{a}_{i,\text{cons}} P_{i\cdot}|$ subject to a non-positive slope, one LP over all jurisdictions coupled by the slope row. Each definition uses a different criterion for the smallest reversal; the second can concentrate departures in neighborhoods with the largest regression weights.

Guaranteed value of a report $S\ell$: $W_S^{\max} = \max\{c^\top(\ell - \ell') : \ell, \ell' \in \Lambda,\ S\ell = S\ell'\}$. For any true allocation ℓ^0, every ℓ with $S\ell = S\ell^0$ forms a feasible pair with it, so the range left after the report is at most $W_S^{\max}$ for every ℓ^0 and equals it for some. It separates into one LP per jurisdiction. *Revealing the direction.* Report S reveals the direction of the slope on Λ iff no two allocations $\ell, \ell' \in \Lambda$ with $S\ell = S\ell'$ have slopes of strictly opposite sign, $\theta(\ell) < 0 < \theta(\ell')$. Allocations with $\theta = 0$ count as neither sign, so full disclosure ($S\ell = S\ell' \Rightarrow \ell = \ell'$) always reveals the direction. Let $t_S^* = \max\{t : \theta(\ell) \le -t,\ \theta(\ell') \ge t,\ S\ell = S\ell',\ \ell, \ell' \in \Lambda\}$, one LP over all jurisdictions. Because the set of pairs is symmetric in (ℓ, ℓ'), a strictly opposite pair exists iff $t_S^* > 0$, and t_S^* is then the largest margin of such a pair. Hence S reveals the direction iff $t_S^* \le 0$. Table C29 reports t_S^*. Under every assumption set and report we consider, $t_S^* > 0$ wherever the current set contains zero; in 2022 under the main assumptions $t_S^* = 0.026$ for residence reporting.

Primary suppression. Let R_k release each integer out-of-zone count P_{ic} exactly when it is at least k, otherwise releasing a suppressed marker. It includes invalid ballots and leaves other pooled modes pooled.

If $R_k(\ell) = R_k(\ell')$, an unsuppressed count agrees and two suppressed counts belong to $\{0, \dots, k-1\}$. Consequently $|S(\ell - \ell')| \le k - 1$ componentwise, where S selects P_{ic}. Let

$$\overline{W}_k = \max\{c^\top(\ell - \ell') : \ell, \ell' \in \Lambda,\ |S(\ell - \ell')| \le k - 1\}.$$

Every same-report integer pair is feasible for this continuous relaxation. Therefore the width left by R_k for any feasible integer allocation is at most $\overline{W}_k$. Relative to the current continuous width W_0, at least $1 - \overline{W}_k/W_0$ of that reported range is removed. This is not a fraction of an exactly solved integer prior range. The relaxation need not be sharp: it also allows differences in counts that would be visible and does not impose common suppression markers. At $k = 1$ it reproduces exact disclosure. Increasing k weakly increases $\overline{W}_k$. Table C30 uses $k \in \{1, 5, 10, 20\}$. The rule excludes complementary suppression of larger cells; no disclosure-risk guarantee is claimed.

A.4 Computation

Each jurisdiction is one LP with $n^2|\mathscr{C}| + 2n|\mathscr{C}| + n$ variables ($|\mathscr{C}| = 6$). All restrictions are built by one routine used by every computation, including the valid-vote programs and the integer checks. Programs are solved with HiGHS through SciPy, with objective coefficients normalized to unit maximum (without it, coefficients of order 10^{-9} fall below the solver's dual tolerance and bounds are reported too narrow) and feasibility tolerances of 10^{-9} and 10^{-10}. Exact dong-level valid-vote bounds use Dinkelbach's (1967) algorithm. Table A1 re-solves selected near-zero lower bounds as mixed-integer programs with a 30-second limit, extended to 180 seconds if no integer allocation is found. These optimization checks exclude the residents' early-composition restriction, for which optimization did not finish within an hour.

Table A1. Integer check of near-zero lower bounds

Cell	LP z lower	Integer z lower (solver bound)	Integer z incumbent	Prop. 4 y lower (integer, solver bound)	y at integer allocation	Solves at time limit
2012 within-district, $\eta = 0$, $\delta = 1$	0.0077	0.0077	0.0077	0.0069	0.0070	0/50
2026 within-district, $\eta = 0.1$, $\delta = 0.1$	0.0137	0.0139	0.0139	0.0098	0.0106	10/50
2026 within-district, calibrated, $\delta = 0.1$	0.0104	0.0106	0.0106	0.0065	0.0072	7/50
2025 within-district, $\eta = 0$, $\delta = 0.1$	0.0017	0.0018	0.0018	−0.0020	−0.0006	2/50
2024 within-constituency, $\eta = 0$, $\delta = 0.1$	0.0036	0.0037	0.0037	0.0078	0.0092	1/96
2022 within-district, $\eta = 0$, $\delta = 0.1$	0.0144	0.0145	0.0145	0.0187	0.0204	3/50

Notes. Mixed-integer programs use the same constraint matrices as the LPs, including the 2026 zones. Each solve has a 30-second limit, extended to 180 seconds when no integer solution has been found. Solver bound: the best bound proven by the solver when it stops, which is a valid lower bound on the integer minimum also when the time limit is reached; the incumbent is the best integer allocation found. These optimization checks exclude the residents' early-composition restriction, for which optimization did not finish within an hour. Integer witnesses for the main specification are reported separately in Table A2.

Table A2 addresses integer feasibility and near-attainability under the main assumptions directly. For each jurisdiction and each continuous endpoint in the four elections from 2022, a zero-objective integer program searches within the endpoint's floor/ceiling box, expanding the box by one and then four ballots if needed, with a three-second limit at each attempt. All 246 searches found integer allocations. A separate checker reads the saved counts and evaluates (R), (S), (Z), the movement cap and both composition restrictions arithmetically, without using the optimization constraint matrices. The witnesses bracket each integer endpoint within 0.0008 of its continuous bound for all Seoul and without the three southeastern districts, less than 0.06 percentage points for a doubling of prices. They establish integer feasibility,

positive and negative attainable slopes in the unresolved cases, and near-attainability, rather than proven integer optimality. The reported continuous bounds remain conservative outer bounds for integer ballots.

Table A2. Integer witnesses under the main assumptions

Election	Scope	Continuous lower	Attained integer lower	Attained integer upper	Continuous upper	Maximum endpoint gap
2022	All Seoul	−0.026166	−0.025631	0.222200	0.222760	0.000559
2022	Without the three	−0.042456	−0.041866	0.203650	0.204264	0.000614
2024	All Seoul	0.001255	0.001890	0.205550	0.206201	0.000651
2024	Without the three	−0.027303	−0.026602	0.183697	0.184425	0.000728
2025	All Seoul	−0.037422	−0.036930	0.193227	0.193832	0.000605
2025	Without the three	−0.063627	−0.063127	0.171855	0.172545	0.000690
2026	All Seoul	0.054294	0.054953	0.155037	0.155658	0.000659
2026	Without the three	0.029233	0.029998	0.138116	0.138813	0.000765

Notes. Within-district z slope, Table 2 column E. The integer minimum lies between the continuous lower bound and the attained integer lower value; the integer maximum lies between the attained integer upper value and the continuous upper bound. Integer allocations are constructed in small boxes around continuous endpoints and verified against the accounting identities, zones, movement and composition inequalities by a separate arithmetic checker. All 246 jurisdiction-by-endpoint witnesses are saved in the replication files. These witnesses establish feasibility and near-attainability, not proven integer optimality.

B. Data

B.1 Returns and rolls. Returns are the National Election Commission's counting-unit files (2012–2025) and counting-unit spreadsheets (2026) (National Election Commission 2026). Each dong contributes its election-day voting districts and its in-zone early station; each gu, or constituency in 2024, its out-of-zone early, at-home (and shipboard) and overseas rows. Certified electorates by dong come from the NEC electorate service; in presidential and mayoral elections its totals equal the counting files' totals in all 25 gu. In presidential elections overseas electors with resident registration are assigned to dongs in E_i and are not on the election-day roll. In 2024 the service exceeds the constituency files by 11,672 electors (0.14%), overseas electors without resident registration who vote only for the party list; they are added to U. U is non-negative in every unit and differs from the published abstentions of the pooled modes by -2 to 57 per gu; positive differences are in-zone early abstentions, and the small negative differences reflect minor inconsistencies between the certified electorate and the counting files. U is small, 0.33%, 0.40%, 0.25% and 0.03% of H in 2022, 2024, 2025 and 2026 (Table C12), and larger in higher-price districts, where more residents are registered abroad; it is allocated among a jurisdiction's dongs without restriction.

Election coverage. The six elections are assembled cases, not a prespecified or exhaustive sample. Other legislative and local contests, including the 2020 National Assembly and 2022 local elections, are outside this dataset. Their omission does not imply unavailable source data. The comparisons therefore concern the included contests, rather than a continuous trend or a representative difference between election types. The estimands use registered residence, which can differ from actual residence for students, soldiers and residents abroad.

In 2022, voters with COVID-19 voted early in a separate session on the second early-voting day or on election day after regular hours; the counting-unit files contain no separate category for these ballots, which are reported within the standard modes and treated accordingly.

B.2 The 2026 zones. When local councils and heads are elected together at the end of their terms, the early-voting zone is the district-council constituency (Regulations on Public Official Elections, Art. 133(3); National Election Commission n.d.); in presidential elections it is the gu, and in National Assembly elections

the constituency where a gu holds two or more (Art. 86(3)). The NEC's table of council constituencies and dongs (*Table of Constituencies and Eup, Myeon and Dong*, 선거구및읍면동현황) assigns each of Seoul's 427 dongs to one of 155 constituencies. For the 113 contested constituencies, the council returns list the same dongs and report out-of-zone early and at-home voters. A voter receives all ballots at once, so out-of-zone status is the same in every contest: wherever all of a gu's constituencies were contested, the council counts sum exactly to the mayoral gu count, and at each of the 320 in-zone early stations of contested constituencies the council and mayoral counts of early voters are equal (Table B1).

Table B1. 2026 early-voting zones: district-council constituencies

Gu	Dongs	Council constituencies	Contested	Out-of-zone early voters in contested constituencies (council returns)	Out-of-zone early voters, gu (mayoral returns)	Sum check where all contested
Gangnam-gu	22	9	7	26,033	33,020	–

Jung-gu	15	4	3	6,290	9,197	–
Jungnang-gu	16	7	5	20,046	25,358	–

Notes. Source: NEC Election Statistics System, constituency-and-dong table and constituency-level council returns. In every gu where all constituencies were contested, the council counts sum exactly to the mayoral gu count. In-zone early voters per station: council and mayoral counts are equal at 320 of 320 stations of contested constituencies.

B.3 Prices. Apartment transactions in the twelve complete calendar months ending before each election month (Ministry of Land, Infrastructure and Transport 2026) are geocoded from lot number to administrative dong through the road-name address service (91% to over 99% matched exactly; the rest by same-lot or nearest-lot majority within the legal dong, or dropped) and mapped to the dong names in force at each election (Yongdu-dong and Sinseol-dong to Yongsin-dong; Gaepo 3-dong to Irwon 2-dong before 2023; the five Sindang dongs to their pre-2014 names in 2012; Sangil 1- and 2-dong to Sangil-dong and Hangdong to Oryu 2-dong in 2017). The regressor is the log median price per square meter. In 2017–2026

the median dong has 70–200 transactions; dongs with fewer than 30 number 99, 38, 96, 109, 62 and 43 in 2012, 2017, 2022, 2024, 2025 and 2026.

The supplied price summaries are frozen analysis inputs. Reconstructing available summaries from the saved trades and current address crosswalk reproduces the 2022, 2024 and 2026 medians. One 2012 and two 2017 medians differ by at most 0.65%; checking accounting-only and minimal-movement/10-point slopes in both geographic scopes changes endpoints by less than 0.00004 and no sign conclusions (supplementary price-construction audit). The original 2025 transaction download and generating code remain unavailable. To audit that year's input, we separately retrieved all 300 Seoul district-months for June 2024–May 2025 from MOLIT on 14 October 2026: 73,319 records, of which 68,448 remain after cancellation flags are excluded. Extending the saved address crosswalk maps 68,356 of these records (99.87%) and yields prices for 421 neighborhoods, compared with 420 in the archived summary; 419 have prices in both. The median absolute price difference on common neighborhoods is 0.003%, but 56 differ by more than 1%; the maximum is 75.4% in Jangchung-dong, with three archived transactions versus two in the rebuild. The two log-price measures correlate at 0.996. These differences can combine source revisions and mapping changes, which this audit cannot separate. Recomputing the A, C, D and E slope ranges changes endpoints by at most 0.012 and leaves their sign conclusions unchanged in both geographic scopes. Table C25 also compares the main setting on common geographic support. Raw XML, request dates and hashes, the extended address map, reconstruction code and comparison files are supplied. This is a reproducible alternative measurement, not recovery of the original snapshot.

B.4 Mobility. Seoul Living Mobility (Seoul Metropolitan Government and KT 2026) reports trips by origin and destination dong, day and hour, with a stay of at least 27 minutes; counts of three or fewer are suppressed. We keep home-origin trips from Seoul arriving 06:00–17:59 on the two weekdays of early voting (Friday and Saturday; Thursday and Friday in 2025), summed over the month's days with those weekdays; a calibration from each day alone gives nearly the same bounds (supplementary day-specific calibration check). For zone u, W_u counts trips to another dong of u and X_u trips leaving u; $R_u = W_u/X_u$ and $C_u = R_u B_u$, with B_u the zone's out-of-zone early ballots (in 2026 the council headcount for contested constituencies, scaled to counted mayoral ballots, and otherwise the gu residual split in proportion to removed residents who did not vote at an in-zone station, $E - D - K$); C_u is allocated to stations by their inflow from other dongs of u. Suppressed counts are set to 2. The mobility data use an older dong system in a few places, where one code covers two election dongs (Sangil 1- and 2-dong; Oryu 2-dong and Hang-dong; Sinseol-dong and Yongdu-dong); trips of such a code are split between its dongs in proportion to their electorates, and in the one 2026 zone that consists only of two such dongs, where movement between them is unobservable, R_u is set to the median of the other zones with two or more dongs. Calibrated flows are a median 9–21% of a station's ballots in 2022–2025 and 4% in 2026.

B.5 Counting rules elsewhere.

Table B2. Counting rules for ballots cast away from the assigned polling place

Country	Smallest unit with candidate totals	Ballots reported above that unit	Usual treatment
Taiwan	Polling station, village	None in general	Read directly; residence-based by household registration
Japan	Counting district (開票区)	All ballots mixed at the counting district	Not reported below the counting district
United States (many states)	Precinct	Absentee, early, provisional ballots (county or city)	Allocated in proportion to in-person votes
Germany	In-person precinct	Postal ballots, counted in postal districts	Analyst's choice
Canada	Polling division	Special-voting-rules ballots (electoral district)	Analyst's choice
Australia	Polling place	Declaration votes (division)	Analyst's choice
Korea	Voting district, dong	Out-of-zone early, at-home, overseas ballots (gu or constituency)	Dropped, allocated or imputed

Sources. Taiwan: Civil Servants Election and Recall Act, Art. 17 (Taiwan n.d.a, n.d.b). Japan: Public Offices Election Act, Arts. 18 and 66(2) (Japan 1950). United States: Amos et al. (2017); Palmer and Schneer (2021). Germany: Bundeswahlordnung § 7 (Germany 2002); postal ballots were 47.3% of ballots in 2021 and 37.0% in 2025 (Die Bundeswahlleiterin 2025). Canada: Canada Elections Act, s. 168(1) (Canada 2000); Elections Canada (2025, Table 5). Australia: Australian Electoral Commission (2025).

C. Evidence by question

The tables are arranged by the claim they assess. Section C.1 separates observed voting-mode patterns from residential allocations. C.2 varies the restrictions needed to extend the observed relationship. C.3 describes feasible reversals. C.4 tests geographic scope, the outcome denominator and measurement. C.5 evaluates statutory zones and reporting changes. All ranges are conditional on the stated inputs and restrictions; they are not confidence intervals. Appendix A2 checks integer feasibility under the main assumptions.

C.1 Observed patterns and initial comparisons

Table C1 gives the directly observed election-day and station benchmarks; C2 the regressions across fully counted districts; and C3 the price-group contrasts. C4 shows how uniform movement restrictions change the resident-based range. Tables C5–C6 describe observed voting-mode gaps. These gaps provide reference scales for restrictions, but do not identify the missing neighborhood composition.

Table C1. Point-identified benchmarks: election-day voters and in-zone early stations

Election	Election-day voters: all	Election-day voters: without the three	In-zone stations: all	In-zone stations: without the three
A. Within-district slope				
2012	0.087	0.057	–	–
2017	0.013	0.001	0.014	−0.004
2022	0.097	0.079	0.091	0.066
2024	0.102	0.078	0.090	0.058
2025	0.063	0.041	0.055	0.029
2026	0.086	0.069	0.102	0.073
B. Higher- minus lower-price half (percentage points)				
2012	1.9	0.9	–	–
2017	0.1	−0.4	0.2	−0.4
2022	4.0	3.2	3.8	2.8
2024	3.8	2.7	3.3	2.1
2025	1.8	1.0	1.8	0.9
2026	3.0	2.2	3.8	2.5
C. Auxiliary diagnostics for the election-day slope: gu-clustered standard error; within-district permutation p-value				
2012	(0.021); p <0.001	(0.020); p <0.001		
2017	(0.011); p 0.096	(0.012); p 0.875		
2022	(0.017); p <0.001	(0.016); p <0.001		
2024	(0.016); p <0.001	(0.013); p <0.001		
2025	(0.015); p <0.001	(0.014); p <0.001		
2026	(0.012); p <0.001	(0.012); p <0.001		

Notes. Conservative candidate's valid-vote share. Election-day ballots are counted in the voter's own voting district, so these slopes and contrasts describe registered residents who voted on election day and need no allocation assumption. In-zone station shares are counted where cast and include voters from other neighborhoods of the zone; 2012 had no in-zone early voting. Weights as in Table 2 (gu fixed effects; median split within gu). Without the three: Gangnam, Seocho and Songpa excluded from the weights. Panel C, auxiliary diagnostics only: the slopes above describe the observed neighborhoods exactly. The permutation p-value (prices permuted within each gu, 5,000 permutations, two-sided) assumes that dongs are exchangeable within a gu and ignores spatial dependence; prices were not randomly assigned. The clustered standard error reads the dongs as draws from a larger population.

Table C2. Regressions across fully counted units (valid-vote share on the unit mean of dong log price)

Election	Units	Slope	HC1 SE	HC3 SE	Permutation p	Leave-one-out range	Excl. Gangnam, Seocho and Songpa: slope (HC3 SE)	Electorate-weighted price: slope (HC3 SE)
2012	25 gu	0.137	0.028	0.035	<0.001	0.111–0.148	0.057 (0.038)	0.138 (0.035)
2017	25 gu	0.060	0.014	0.017	<0.001	0.048–0.065	0.025 (0.025)	0.061 (0.018)
2022	25 gu	0.197	0.028	0.033	<0.001	0.175–0.207	0.131 (0.022)	0.203 (0.034)
2024	24 units	0.172	0.033	0.038	<0.001	0.151–0.193	0.097 (0.039)	0.175 (0.038)
2024	48 constituencies	0.181	0.023	0.025	<0.001	0.168–0.194	0.099 (0.025)	0.183 (0.025)
2025	25 gu	0.137	0.023	0.028	<0.001	0.118–0.147	0.080 (0.022)	0.139 (0.028)
2026	25 gu	0.142	0.026	0.030	<0.001	0.123–0.153	0.086 (0.028)	0.145 (0.031)

Notes. 2024: Jung-gu and Seongdong-gu merged because one constituency spans both. Slopes describe the fully counted units themselves and need no allocation assumption. The standard errors and permutation p-values (5,000 permutations) answer a different question: how far the slope would vary if district values were draws from a larger population or if prices were assigned to districts at random. They are reported for that reading only; the identified sets of the main analysis condition on the observed returns and involve no sampling.

Notes. Accounting only: movement unrestricted ($\eta = 1$, at which the cap $r_j + K_j$ cannot bind) and $\delta = 1$. $\delta_{\min}$: each jurisdiction at its smallest feasible out-of-zone band. η^*: largest η at which the lower bound is positive, lower end of a bisection interval of width 1/512 on [0, 1] ("any": positive at $\eta = 1$). 2026 imposes the statutory early-voting zones.

Table C5. Is the early-vote gap related to price or age? (conservative share; coefficients, standard errors in parentheses)

Election	Gu: in-zone early − election day, on log price	on share aged 60+	Gu: out-of-zone early − election day, on log price	on share aged 60+	Dong (within gu): station departure, on log price	on share aged 60+	Mean gu gap γ^K (SD)
2017	−0.014 (0.008)	0.055 (0.070)	−0.009 (0.011)	−0.037 (0.075)	0.000 (0.005)	0.026 (0.025)	−0.043 (0.008)
2022	−0.001 (0.010)	0.130 (0.076)	−0.042 (0.021)	−0.139 (0.085)	−0.008 (0.006)	0.010 (0.021)	−0.101 (0.010)
2024	−0.021 (0.007)	0.046 (0.059)	−0.029 (0.009)	−0.081 (0.075)	−0.019 (0.006)	−0.010 (0.026)	−0.120 (0.014)
2025	−0.072 (0.012)	−0.179 (0.109)	−0.058 (0.013)	−0.361 (0.110)	−0.011 (0.007)	−0.042 (0.025)	−0.282 (0.024)
2026	−0.025 (0.006)	−0.022 (0.088)	−0.037 (0.010)	−0.257 (0.068)	0.012 (0.007)	−0.010 (0.022)	−0.263 (0.013)

Notes. Gu level: one observation per jurisdiction (48 constituencies in 2024), joint regression on price and age, HC3 standard errors. Dong level: weighted by station ballots, jurisdiction fixed effects, standard errors clustered by jurisdiction. Stations mix residents and movers, so the dong-level test is an imperfect proxy. Age shares from April 2026 resident registration for all elections.

Table C6. Out-of-zone and in-zone early voters by counting jurisdiction (conservative valid-vote share, percentage points)

Election	Jurisdictions	Out-of-zone minus in-zone: median	Range	Largest absolute gap	In-zone stations: median absolute deviation from their jurisdiction	Largest station deviation
2017	25	−3.5	−5.4 to −0.6	5.4	1.7	14.8
2022	25	1.7	−3.2 to 3.4	3.4	2.2	19.9
2024	48	−2.5	−6.0 to 0.1	6.0	1.8	19.2
2025	25	0.4	−2.3 to 2.7	2.7	1.4	21.9
2026	25	3.6	1.7 to 7.7	7.7	1.9	25.7

Notes. Each jurisdiction's out-of-zone early ballots are published as one total, so the first three columns describe whole districts (constituencies in 2024). The tolerance δ bounds the same difference for each neighborhood's residents, which is not observed and may vary more within a district than these district-level gaps; the station columns show how far neighborhoods' in-zone shares depart from their district's in-zone share. These are references for δ, not tests of it.

C.2 Which restrictions establish the direction?

Tables C7–C9 vary movement and composition jointly, for all Seoul and outside the three districts. C10 evaluates compatibility with the counts, C11 changes the out-of-zone benchmark, and C12 varies additional composition restrictions. C13 evaluates a separate price-alignment restriction. These exercises describe the conditions for each conclusion; agreement across them does not validate an unobserved allocation.

Table C7. Calibrated movement, residents' early composition unrestricted (z)

Notes. s*: the largest slack s at which the lower end of the range of the within-district slope (or of the higher-minus-lower-price contrast) is positive, with movement and the out-of-zone tolerance held fixed; bisection width 0.0012, lower end reported. The main setting uses s = 0.02, so a relation is established there when s* exceeds 0.02. ∞: positive however much residents' early ballots depart; none: not positive for any s.

Distance from refutation. For each counting jurisdiction, we find the smallest feasible out-of-zone band with calibrated movement and residents' in-zone slack $s = 0.02$ held fixed. Bisection returns a feasible

upper endpoint within 0.00001 of the threshold. An empty feasible set means that the restriction contradicts the observed counts, not that a slope is identified. Table C10 adds the same excess tolerance to these jurisdiction-specific thresholds. This separates compatibility with the counts from the constant-band comparison in Table 2. Because some new bands may be smaller and others larger than 0.10, the main and alternative models are not generally nested. Neither compatibility nor stability across these scenarios establishes that a restriction holds for the unobserved ballots.

Table C10. Out-of-zone tolerance measured from the feasibility boundary

Excess tolerance	Largest minimum band	Smallest main-band margin	All Seoul	Without the three districts
2022				
0.02	0.0306	0.0694	[0.002, 0.198]	**[−0.013, 0.180]**
0.05	0.0306	0.0694	**[−0.010, 0.208]**	**[−0.026, 0.190]**
0.10	0.0306	0.0694	**[−0.031, 0.228]**	**[−0.049, 0.210]**
2024				
0.02	0.0463	0.0537	[0.028, 0.183]	[0.001, 0.161]
0.05	0.0463	0.0537	[0.016, 0.193]	**[−0.012, 0.171]**
0.10	0.0463	0.0537	**[−0.004, 0.211]**	**[−0.033, 0.190]**
2025				
0.02	0.0606	0.0394	**[−0.018, 0.177]**	**[−0.044, 0.156]**
0.05	0.0606	0.0394	**[−0.034, 0.191]**	**[−0.061, 0.171]**
0.10	0.0606	0.0394	**[−0.059, 0.214]**	**[−0.088, 0.195]**
2026				
0.02	0.0732	0.0268	[0.069, 0.141]	[0.044, 0.124]
0.05	0.0732	0.0268	[0.057, 0.152]	[0.032, 0.136]
0.10	0.0732	0.0268	[0.040, 0.170]	[0.012, 0.155]

Notes. Calibrated movement and residents' in-zone composition slack s=0.02 are held fixed. Each jurisdiction's minimum out-of-zone band is found by bisection (feasible upper endpoint; width <=0.00001). The main-band margin is 0.10 minus that minimum. Bounds use the jurisdiction-specific minimum plus the stated excess tolerance, capped at one. Thus these scenarios need not nest the constant 0.10 scenario. Compatibility with the counts is not validation of a restriction. Ranges concern the within-district roll-based slope; bold ranges include zero.

Table C11. The benchmark for out-of-zone voters (within-district slope, mobility-calibrated movement, ±10 points)

Benchmark	Smallest feasible tolerance, median (2022/2024/2025/2026)	2022	2024	2025	2026	2022, + residents' early ballots	2024	2025	2026
station shares (main)	0.025 / 0.020 / 0.062 / 0.044	**[−0.283, 0.448]**	**[−0.185, 0.372]**	**[−0.283, 0.411]**	[0.010, 0.201]	**[−0.026, 0.223]**	[0.001, 0.206]	**[−0.037, 0.194]**	[0.054, 0.156]

shifted by gap and its price relation	0.001 / 0.001 / 0.001 / 0.002	**[−0.284, 0.448]**	**[−0.186, 0.373]**	**[−0.283, 0.411]**	[0.006, 0.202]	**[−0.035, 0.217]**	[0.001, 0.207]	**[−0.037, 0.196]**	[0.050, 0.157]

Table C12. Further restrictions: the out-of-zone tolerance, movers' composition and price-aligned out-of-zone departures (within-district slope, z)

Election	δ* at s = 0.02: all	δ*: without the three	s = 0.02 and movers within 10 points: all	Same, without the three	κ_P*: all	κ_P*: without the three	U, share of H
2022	0.037	none	**[−0.025, 0.222]**	**[−0.042, 0.203]**	0.007	none	0.33%
2024	0.102	none	[0.003, 0.202]	**[−0.026, 0.179]**	0.015	none	0.40%
2025	none	none	**[−0.037, 0.193]**	**[−0.063, 0.172]**	<0.001	none	0.25%
2026	0.261	0.176	[0.060, 0.153]	[0.033, 0.135]	0.082	0.060	0.03%

Notes. Mobility-calibrated movement throughout. δ*: the largest out-of-zone tolerance at which the lower end of the range stays positive with s = 0.02 (none: not positive at the smallest feasible tolerance). Movers: residents who voted at another station of their zone vote within 10 points of their home station's composition, with s = 0.02 and δ = 0.1 (5 points gives nearly the same ranges). κ_P*: with δ removed and s = 0.02, the largest bound on the within-jurisdiction slope of residents' out-of-zone departures from their station's composition on log price at which the slope stays positive. U: removed residents who cast no counted ballot (allocated without restriction), as a share of H.

Price-aligned departures. A reversal requires residents' early votes in higher-price neighborhoods to be systematically less conservative than their neighborhoods' election-day votes imply, but the symmetric restrictions let each neighborhood depart independently. We therefore ask what a different restriction would imply: within each counting jurisdiction, the slope of residents' early-vote departures (in-zone and out-of-zone, as a share of the roll) on log price may not exceed κ in absolute value (Online Appendix A.1 and Table C13). With the out-of-zone tolerance removed, the slope among all residents stays positive for κ up to 0.042, 0.038, 0.032 and 0.095 in 2022, 2024, 2025 and 2026, and up to 0.028, almost zero, 0.011 and 0.075 outside the three districts. Two observable patterns give a scale, though neither measures residents' unobserved departures: the same slope for in-zone station ballots, which also count non-residents, is at most 0.016, 0.047, 0.026 and 0.013 in absolute value across jurisdictions, and the slope implied if early-vote gaps varied with price within counting jurisdictions as they do across them (districts; constituencies in 2024) is 0.007, 0.008, 0.021 and 0.006. For all of Seoul κ^* exceeds both scales in 2022, 2025 and 2026 and the between-jurisdiction one in 2024; outside the three districts it exceeds both in 2022 and 2026 and neither in 2024 and 2025. Bounding only the alignment of out-of-zone departures orders the elections similarly (Table C12). These results identify the additional assumption that would settle the undetermined signs; they do not show that it holds.

Table C13. How far residents' early-vote departures may align with price before the within-district slope loses its sign

Election	κ^*: all, out-of-zone ± 10	κ^*: all, out-of-zone unrestricted	κ^*: without the three, ± 10	κ^*: without the three, unrestricted	Station gradient: median	Station gradient: largest absolute	Between-jurisdiction reference
2022	0.042	0.042	0.028	0.028	−0.003	0.016	0.007
2024	0.052	0.038	0.015	<0.001	−0.003	0.047	0.008
2025	0.032	0.032	0.011	0.011	−0.001	0.026	0.021
2026	∞	0.095	0.091	0.075	0.004	0.013	0.006

Notes. Mobility-calibrated movement; the restriction on residents' early-vote composition (s) is replaced by $|g_u| \leq \kappa$, where g_u is the slope, within counting jurisdiction u, of residents' early-vote departures from their benchmarks (in-zone and out-of-zone, as a share of the roll) on log price. κ^*: the largest κ at which the lower end of the within-district slope range stays positive (bisection width 0.0002; ∞: positive without the restriction). Station gradient: the same slope computed for observed in-zone station ballots, over jurisdictions; stations also count non-residents. Between-jurisdiction reference: the slope residents' departures would have if, within jurisdictions, early-vote gaps varied with price as they do across counting jurisdictions (gu; National Assembly constituencies in 2024), $|b_K|$ (in-zone early ballots / H) + $|b_B - b_K|$ (out-of-zone ballots / H), with b_K and b_B the cross-district slopes of the in-zone and out-of-zone early minus election-day gaps on log price. The slope is identified as positive when residents' departures are no more aligned with price than κ^*.

C.3 What would a reversal require?

Table C14 summarizes the first-reversal threshold and least-departure exercise. C15 and C16 give their distinct allocation profiles; C17 restricts movers' composition. Each minimum uses its stated criterion with other restrictions fixed. The allocations are witnesses to what the model permits, rather than estimates of actual behavior.

Table C14. Assumptions and allocations that permit a non-positive slope

Election	Out-of-zone voters within (points)	Largest additional tolerance s with a positive slope	First reversing allocation: movers minus stayers, conservative share (points)	Fewest residents' early ballots that must depart to reverse
2022	10	none	12 to 21	16,685
2022	20	none	14 to 18	15,340
2024	10	0.021	11 to 17	32,177
2024	20	none	9 to 14	30,103
2025	10	none	20 to 24	13,539
2025	20	none	21 to 23	12,512
2026	10	∞	no reversal	no reversal
2026	20	0.087	−2 to 24	69,384

Notes. Mobility-calibrated movement. s: residents' early ballots may depart from their neighborhood benchmark (election-day share shifted by the district's early-vote gap) by their station's departure plus s; ∞: positive however much they depart; none: not positive even when they depart only as much as their station. First reversing allocation: the one with the lowest slope at s just above that value; movers voted at another station of their zone, stayers at their own; range over price terciles. Last column: among allocations with a non-positive slope, the fewest residents' conservative early ballots departing from the benchmark (out-of-zone departures and concentration in Online Appendix Table C16). Each reversal is minimal only in its own metric, with other assumptions fixed.

Table C15. First allocation with a non-positive slope as s increases ($\lambda = 1$)

Election	δ	s at edge	Tercile	Movers' share	Movers' conservative share	Stayers' conservative share	Residents' early conservative share	a^F	Station share	Median |departure| of residents' early share from a^F (this allocation)	90th pct.

Notes. a^F: the neighborhood benchmark for residents' early conservative share. At s just above s*(1, δ), the allocation attaining the minimum slope. Departures of residents' early composition from a^F are bounded by the station's own departure plus s in every dong. Rows only where the edge exists (s* finite).

Table C16. Least-departure reversal: components and concentration (within-district, calibrated movement)

Election	δ	Residents' early ballots departing	Dongs with > 10	Largest in one dong	Share in top-decile-leverage dongs	Out-of-zone ballots departing	Needed for feasibility	Dongs with > 10	Share in top-decile-leverage dongs
2022	0.1	16,685	31	1,710	95%	5,366	2,015	30	32%
2022	0.2	15,340	31	1,410	94%	6,336	2,015	27	49%
2022	1	8,659	27	892	100%	12,152	2,015	22	71%
2024	0.1	32,177	62	2,218	61%	11,397	8,312	72	5%
2024	0.2	30,103	58	2,218	63%	12,534	8,312	60	11%
2024	1	17,966	55	1,210	62%	23,393	8,312	63	41%
2025	0.1	13,539	26	2,197	96%	3,554	1,063	24	36%
2025	0.2	12,512	26	2,197	96%	4,377	1,063	19	55%
2025	1	8,452	23	1,442	98%	8,162	1,063	21	72%
2026	0.2	69,384	268	1,303	15%	64,253	18,583	244	10%
2026	1	17,423	167	461	20%	59,329	18,583	108	39%

Notes. Departing ballots: absolute departure of residents' conservative ballots from a^F (in-zone early) or from the station anchor (out-of-zone). Needed for feasibility: the smallest out-of-zone departure of any allocation in Lambda, without the slope constraint. Leverage: $|w_i|/H_i$.

Table C17. Restricting how movers vote: residents who voted at another station vote within t of their home station's shares (within-district slope; mobility-calibrated movement, ± 10 points)

t	2022	2024	2025	2026
0.05	**[−0.113, 0.319]**	**[−0.052, 0.260]**	**[−0.106, 0.270]**	[0.054, 0.162]

0.3	**[−0.192, 0.393]**	**[−0.115, 0.321]**	**[−0.186, 0.340]**	[0.033, 0.182]

C.4 Geographic reach, denominator and measurement

Table C18 compares geographic scopes under columns A–E. C19 combines exclusion of the three south-eastern districts with price-tail trimming. Tables C20–C21 test the valid-vote denominator and C22 age adjustment and tercile contrasts. C23 varies price specifications, coverage and weights; C24 resamples transactions; C25 checks the alternative 2025 price reconstruction; and C26 changes the candidate outcome. The loss of a positive bound in a comparison is retained as evidence about the claim's scope.

Table C18. Beyond Gangnam: the within-district relation without Gangnam, Seocho and Songpa

Election	Conv.	(A) Returns and rolls only	(B) Minimal movement	(C) = (B) + out-of-zone within 10 points	(D) Mobility-calibrated	(E) Main
A. Within-district slope without Gangnam, Seocho and Songpa (z)						
2012	0.058	**[−0.021, 0.129]**	**[−0.021, 0.129]**	[0.001, 0.110]	–	–

Notes. Columns as in Table 2; roll-based share z. Valid-vote shares: Table C21.

Price tails beyond the three districts. Table C19 combines exclusion of Gangnam, Seocho and Songpa with trimming the highest-price neighborhoods among those remaining. The cutoff is computed within the 357 priced neighborhoods outside the three districts; all accounting constraints are retained. Trimming changes the target population, so these comparisons assess the geographic and price-distribution scope of the relation. The separate leave-one-district-out check keeps a positive lower bound for every remaining district omitted under the main assumptions.

Table C19. Price-tail sensitivity outside Gangnam, Seocho and Songpa, 2026

Additional price exclusion	Priced neighborhoods	Within-district slope range
Residents composition slack s = 0.02		
None	357	[0.0292, 0.1388]
Top 5%	339	[0.0004, 0.1304]
Top 10%	321	**[−0.0093, 0.1302]**
Residents composition slack s = 0.05		
None	357	[0.0168, 0.1514]
Top 5%	339	**[−0.0147, 0.1454]**
Top 10%	321	**[−0.0257, 0.1467]**

Notes. Mobility-calibrated movement and out-of-zone tolerance delta = 0.10. Price cutoffs are computed among the 357 priced neighborhoods outside the three districts, and every accounting constraint is retained. Ranges are continuous-allocation bounds for z; bold ranges include zero. Separately omitting each of the other 22 districts at s = 0.02 yields lower bounds from 0.0187 to 0.0338, all positive. Full district results are in the replication files.

Table C20. Valid-vote shares: within-district slope

Election	Assumptions	Roll-based share (continuous range)	Valid-vote share, lower end: [outer bound, attainable]	upper end: [attainable, outer bound]
2012	returns and rolls only	[0.008, 0.157]	[0.0069, 0.0070]	[0.1577, 0.1579]

Notes. Ranges and attainable values in this table concern continuous allocations; integer checks are separate (Table A2). The exact lower end of the valid-vote range lies between the two numbers given; it is negative, so the direction is not established, when the attainable value is negative.

Table C21. Valid-vote slope lower bounds with and without the three southeastern districts

Election	Slope: all	Slope: without the three	Contrast (points): all	Contrast (points): without the three
2022	[−0.026, −0.024]	[−0.044, −0.042]	[−3.3, −3.2]	[−4.0, −3.9]
2024	[0.004, 0.005]	[−0.026, −0.025]	[−1.5, −1.4]	[−2.7, −2.6]
2025	[−0.046, −0.045]	[−0.072, −0.071]	[−4.7, −4.6]	[−5.6, −5.5]
2026	[0.049, 0.050]	[0.024, 0.024]	[0.4, 0.5]	[−0.6, −0.6]

Notes. Attainable values refer to feasible continuous allocations; integer checks are reported separately in Table A2. Each entry gives a guaranteed outer bound and an attainable value for the lower end of the valid-vote range; the exact lower end lies between them. The direction is established when the first value is positive and not established when the second is negative.

Table C22. Within-district relation with age composition held fixed, and the tercile contrast

Election	All of Seoul: election-day voters	All of Seoul: all residents, main assumptions	Without the three: election-day voters	Without the three: all residents, main assumptions
Slope				
2022	0.097	**[−0.026, 0.223]**	0.079	**[−0.042, 0.204]**

2026	Citywide	calibrated	–	[0.092, 0.174]	0.001, 0.001	0.007, 0.006	[0.054, 0.205]	100%	200

Notes. The returns, rolls and movement caps, which define the polytope, are held fixed. Transactions resampled: each dong's median price is recomputed from a resample of its transactions; this measures sensitivity to price measurement. Dongs and transactions resampled: dongs are also resampled with replacement within jurisdictions, which duplicates high-leverage dongs and mechanically pushes the extrema outward, so these columns overstate instability and are not confidence intervals.

Newly reconstructed 2025 prices. Table C25 holds the electoral inputs and allocation restrictions fixed and replaces the archived price summary with a separately reconstructed summary (Appendix B.3). Both price definitions are evaluated on their available neighborhoods. The exercise checks the sensitivity of the historical results; it does not recover the original download or establish the correctness of every historical address assignment.

Table C25. 2025 slopes using prices rebuilt from a newly retrieved source snapshot

Assumption column	Archived price summary	Rebuilt price summary
All Seoul		
A	**[−0.468, 0.552]**	**[−0.461, 0.550]**
C	[0.002, 0.149]	[0.002, 0.148]
D	**[−0.283, 0.411]**	**[−0.279, 0.408]**
E	**[−0.037, 0.194]**	**[−0.036, 0.192]**
E, common support (n=419)	**[−0.037, 0.194]**	**[−0.038, 0.193]**
Without the three districts		
A	**[−0.523, 0.557]**	**[−0.512, 0.554]**
C	**[−0.026, 0.127]**	**[−0.025, 0.126]**
D	**[−0.317, 0.400]**	**[−0.311, 0.396]**
E	**[−0.064, 0.173]**	**[−0.061, 0.171]**
E, common support (n=353)	**[−0.063, 0.172]**	**[−0.065, 0.172]**

Notes. Columns A, C, D and E follow Table 2. The alternative uses June 2024-May 2025 MOLIT records retrieved on 14 October 2026 and a separately extended address crosswalk. It does not reconstruct the original download or generating code. Rows A-E use each source's available neighborhoods; the final row restricts both regressions to their common priced neighborhoods. Appendix B.3 reports coverage and measurement differences. Accounting and composition restrictions are unchanged. The historical analysis inputs are retained. Ranges concern the within-district roll-based slope; bold ranges include zero.

Table C26. Alternative outcomes (z)

Election	Outcome	Slope	Conventional	Returns and rolls only	Minimal movement (η = 0)
2012	Democratic	Citywide	−0.122	[−0.152, −0.088]	[−0.152, −0.088]

calibrated, δ=0.1, s=0.02	Citywide	[0.103, 0.162]	[0.111, 0.154]	[0.112, 0.153]

Notes. Zones: an in-zone early ballot can be cast only at a station in the voter's district-council constituency (155 constituencies). Council-contest headcounts: the out-of-zone early and at-home headcounts that the district-council returns report by constituency (113 contested constituencies; the uncontested ones only as a gu residual), imposed as ranges that allow for unreturned envelopes. Calibrated rows use the zone-level calibration.

Table C28. Guaranteed share of the within-district range removed, by reporting change

Election	Assumptions	Current range	All pooled modes by neighborhood	Out-of-zone early only (proposal)	Headcounts only	Both
2017	minimal movement	0.298	97%	85%	0%	22%
2022	minimal movement	0.364	92%	76%	0%	10%
2022	half the mobility-calibrated movement	0.692	29%	24%	0%	10%
2022	mobility-calibrated movement	0.841	20%	16%	0%	10%
2022	mobility-calibrated movement, residents resemble	0.591	82%	69%	6%	89%
2022	mobility-calibrated movement, ±10 points	0.731	8%	4%	3%	7%
2022	mobility-calibrated movement, ±10 points, residents resemble	0.249	57%	27%	3%	70%
2024	minimal movement	0.331	92%	83%	0%	12%
2024	half the mobility-calibrated movement	0.577	34%	30%	0%	12%
2024	mobility-calibrated movement	0.676	25%	22%	0%	12%
2024	mobility-calibrated movement, residents resemble	0.508	79%	72%	13%	88%
2024	mobility-calibrated movement, ±10 points	0.557	9%	6%	4%	8%
2024	mobility-calibrated movement, ±10 points, residents resemble	0.205	49%	30%	6%	63%
2025	minimal movement	0.335	94%	80%	0%	21%

Election	Assumptions	Current range	All pooled modes by neighborhood	Out-of-zone early only (proposal)	Headcounts only	Both
2025	half the mobility-calibrated movement	0.665	28%	23%	0%	21%
2025	mobility-calibrated movement	0.787	20%	18%	0%	21%
2025	mobility-calibrated movement, residents resemble	0.532	83%	70%	16%	88%
2025	mobility-calibrated movement, ±10 points	0.694	9%	6%	6%	15%
2025	mobility-calibrated movement, ±10 points, residents resemble	0.231	61%	32%	4%	68%
2026	minimal movement	0.280	99%	95%	1%	44%
2026	half the mobility-calibrated movement	0.379	74%	71%	1%	44%
2026	mobility-calibrated movement	0.404	69%	66%	1%	44%
2026	mobility-calibrated movement, residents resemble	0.347	91%	87%	4%	93%
2026	mobility-calibrated movement, ±10 points	0.191	33%	27%	10%	23%
2026	mobility-calibrated movement, ±10 points, residents resemble	0.101	69%	57%	7%	72%

Notes. Out-of-zone voters are unrestricted unless ±10 points is stated. All pooled modes and Out-of-zone early only: share of the current range in the same row removed. Headcounts only and Both: share removed of the range under the same composition assumptions but with movement unrestricted, since a headcount report replaces the movement assumption. Whether a report reveals the direction of the slope: Table C29.

Table C29. Opposite-signed slopes compatible with the same report: maximum margin t*

Election	Assumptions	Residence reporting	Out-of-zone only	Residence + headcounts (no movement assumption)
2022	mobility-calibrated movement	0.337	0.342	0.594
2022	+ residents' early ballots (s = 0.02)	0.053	0.090	0.042
2022	+ out-of-zone ±10 points	0.283	0.283	0.591
2022	main (Table 2, column E)	0.026	0.026	0.032
2024	mobility-calibrated movement	0.248	0.248	0.545
2024	+ residents' early ballots (s = 0.02)	0.052	0.071	0.043
2024	+ out-of-zone ±10 points	0.185	0.185	0.527
2024	main (Table 2, column E)	revealed	revealed	0.019
2025	mobility-calibrated movement	0.315	0.325	0.404
2025	+ residents' early ballots (s = 0.02)	0.045	0.079	0.041
2025	+ out-of-zone ±10 points	0.283	0.283	0.404
2025	main (Table 2, column E)	0.035	0.037	0.033
2026	mobility-calibrated movement	0.064	0.069	0.200
2026	+ residents' early ballots (s = 0.02)	0.016	0.022	0.018
2026	+ out-of-zone ±10 points	revealed	revealed	0.168
2026	main (Table 2, column E)	revealed	revealed	revealed

Notes. t* = max t subject to $\theta(\ell) \leq -t$, $\theta(\ell') \geq t$, $S\ell = S\ell'$, with ℓ and ℓ' in Λ. A report reveals the direction iff no two allocations it cannot distinguish have slopes of strictly opposite sign, that is iff t* ≤ 0 ("revealed"). Where the current set already excludes zero every report reveals the direction; the last column drops the movement assumption, as in Online Appendix Table C28.

Primary suppression changes the information in a residence report. Table C30 evaluates the explicit rule in Appendix A.3. The percentages compare a conservative upper bound on remaining integer uncertainty with the current continuous range; they do not assume that suppressed cells are known exactly.

Table C30. Conservative reporting gains with primary suppression

Election	Current width	Exact counts	Suppress counts <5	Suppress counts <10	Suppress counts <20
2022	0.249	26.9%	26.2%	25.3%	23.7%
2024	0.205	29.7%	29.0%	28.3%	26.8%
2025	0.231	31.9%	31.4%	30.7%	29.6%
2026	0.101	57.1%	55.3%	53.2%	49.0%

Notes. Main assumptions, within-district z slope. Out-of-zone early counts by registered neighborhood and candidate, including invalid ballots; other pooled modes stay pooled. Exact counts reproduce Table 5. Other columns express guaranteed reductions relative to the current continuous range, using an upper bound on remaining integer uncertainty under a release that shows counts >=k exactly and marks smaller counts suppressed. A continuous paired-allocation relaxation allows each count to differ by up to k-1 and can overstate the maximum remaining width. These are not sharp suppression bounds or fractions of an exactly solved integer prior range. Complementary suppression of larger cells and a full privacy assessment are not covered (Appendix A.3).

D. A published allocation

A polling firm's research note on the 2026 local elections (Lee 2026) reported dong-level correlations between apartment prices and Oh Se-hoon's share in Seoul of 0.84 citywide and 0.71 within gu, and a within-gu slope of about 1.9 points per 10 million won per pyeong. We followed its description: residents' pooled-mode counts from the roll difference, with at-home counts in proportion to registered at-home voters; out-of-zone ballots at the dong's in-zone early composition; at-home ballots at the dong's overall composition; columns rescaled to the gu × candidate totals; integers by largest remainder; mean price per pyeong over June 2025 to May 2026. On 423 dongs (424 in the original) this gives 0.842, 0.709 and 1.88, matching the reported figures to their precision.

The replication permits three separate checks. The allocation reproduces the official gu totals by construction. Its premise that residents' out-of-zone ballots have their station's composition cannot hold exactly, because out-of-zone early voters were more favorable to Oh than in-zone early voters in every gu (median 3.6 points, Table C6); the rescaling changes the premise. The allocation does not satisfy every accounting restriction: its constituency-level out-of-zone headcounts are within a median 0.4% of the council returns' counts, but in 47 of 155 constituencies they exceed what the roll leaves for pooled ballots and non-voting, by a median of 16 voters (Table D1). Its slope of 1.88 lies inside every identified set in Table D2, including the set under the paper's main assumptions ($[1.16, 2.54]$), so its positive slope is compatible with the range identified under the main assumptions in 2026.

Table D1. Admissibility of the published 2026 allocation

Gu	Smallest η making it feasible, movement anywhere in the gu	Constituencies where it assigns more pooled voters than the roll allows	Largest excess (voters)	Smallest station-anchor band, $\eta = 10$	Out-of-zone minus in-zone early conservative share
Gangnam-gu	0.023	5 of 9	56	0.004	+0.044
Gangdong-gu	0.005	1 of 7	73	0.008	+0.035
Gangbuk-gu	0.000	0 of 4	–	0.023	+0.023
Gangseo-gu	0.010	3 of 8	30	0.042	+0.044
Gwanak-gu	0.008	3 of 7	28	0.056	+0.050

Gu	Smallest η making it feasible, movement anywhere in the gu	Constituencies where it assigns more pooled voters than the roll allows	Largest excess (voters)	Smallest station-anchor band, η = 10	Out-of-zone minus in-zone early conservative share
Gwangjin-gu	0.005	1 of 4	21	0.021	+0.040
Guro-gu	0.006	2 of 6	2	0.032	+0.035
Geumcheon-gu	0.001	1 of 4	5	0.031	+0.029
Nowon-gu	0.004	2 of 6	3	0.047	+0.055
Dobong-gu	0.002	1 of 5	4	0.021	+0.016
Dongdaemun-gu	0.010	2 of 6	79	0.035	+0.040
Dongjak-gu	0.007	1 of 7	72	0.021	+0.026
Mapo-gu	0.010	4 of 8	37	0.039	+0.042
Seodaemun-gu	0.005	1 of 5	477	0.029	+0.031
Seocho-gu	0.005	3 of 5	38	0.004	+0.023
Seongdong-gu	0.009	1 of 4	16	0.031	+0.053
Seongbuk-gu	0.005	1 of 7	21	0.029	+0.036
Songpa-gu	0.022	4 of 10	43	0.005	+0.032
Yangcheon-gu	0.005	3 of 8	87	0.021	+0.036
Yeongdeungpo-gu	0.011	2 of 7	27	0.015	+0.037
Yongsan-gu	0.013	2 of 5	51	0.026	+0.027
Eunpyeong-gu	0.003	1 of 8	2	0.031	+0.029
Jongno-gu	0.004	1 of 4	126	0.052	+0.076
Jung-gu	0.016	1 of 4	5	0.010	+0.027
Jungnang-gu	0.006	1 of 7	278	0.029	+0.024

Notes. Feasibility fixes the allocation's dong-level pooled ballots and asks whether some in-zone movement and non-voting reproduce (R) and (S). Under the statutory zones, a constituency's pooled voters plus non-voters must equal its removed residents minus its in-zone early ballots.

Table D2. The published 2026 allocation and the identified range (within-district slope, percentage points per 10 million won per pyeong)

Specification	Movement	Out-of-zone tolerance	Range consistent with data	Published allocation
gu FE	returns and rolls only	none	**[−3.29, 6.45]**	1.88
gu FE + age	returns and rolls only	none	**[−3.30, 6.45]**	1.88
